

AN EMPIRICAL INVESTIGATION · N = 10,000

Does less sleep mean *more coffee*?

Testing whether sleep duration predicts daily coffee consumption across 10,000 adults — and how strong the effect actually is.

−0.19 PEARSON R (SLEEP × COFFEE)	< 0.001 P-VALUE STATISTICAL SIGNIFICANCE	+40% MORE COFFEE SHORT VS LONG SLEEPERS	10k RESPONDENTS GLOBAL SAMPLE

VERDICT

THE ANSWER

Yes — but the effect is **small**. Short sleepers drink about **0.80 more cups** per day than long sleepers. The relationship is real, but sleep is **only one piece** of why people reach for coffee.

H₀ REJECTED

r² ≈ 3.6%

n = 10,000

01 · THE METHOD Three tests, one answer Pearson correlation for the linear relationship, Spearman as a robustness check, and a one-way ANOVA across short/normal/long sleep groups. All three rejected H₀ at p < 0.001.	02 · THE ROBUSTNESS It holds everywhere The negative correlation between sleep and coffee appears in every subgroup tested — across genders, stress levels, and occupations. Sleep quality shows the same pattern as sleep quantity, strengthening the result.	03 · THE CAVEAT Correlation ≠ causation The data cannot say whether poor sleep drives people to coffee, or whether coffee disrupts sleep. Both are plausible. A longitudinal study tracking individuals over time would be needed to settle the direction.
